

TGAP prediction impacts, reported separately for each model  
 Bridge Width, Density and Churn share a panel within a model because their perturbations are comparable under the matched-delta protocol. Centralization and Bridge Trend occupy their own rows: their perturbation units are not comparable with the relative-delta concepts, nor with each other. Every panel has its own x-axis because prediction scales differ across models and datasets.  
 The figure is descriptive and gives no global ranking of transformations; formal matched comparisons are reported in RQ1b.
